## NEWS & ANNOUNCEMENTS

The discovery that 2001 QC298 is a possible binary TNO was announced in IAUC 8034 by Noll et al.. The object appears elongated in four HST/NICMOS images, with image analysis suggesting two components with separation of  $0.17 \pm 0.08$  arcsec ( $5000 \pm 2000$  km).

IAUC: <http://cfa-www.harvard.edu/iauc/08000/08034.html>

.....  
There were 34 new TNO discoveries announced since the previous issue of the *Distant EKOs* Newsletter:

2002 VA95, 2002 VB95, 2002 VC95, 2002 VD95, 2002 VE95, 2002 VZ94, 2002 MS4,  
2002 VR128, 2002 VD130, 2002 VE130, 2002 VF130, 2002 VS130, 2002 VT130,  
2002 VU130, 2002 VA131, 2002 VB131, 2002 VC131, 2002 VD131, 2002 VE131,  
2002 VF131, 2002 VV130, 2002 VW130, 2002 VX130, 2002 VY130, 2002 VZ130,  
2002 XD91, 2002 XE91, 2002 XF91, 2002 XG91, 2002 XH91, 2002 XJ91, 2002 WC19,  
2002 XV93, 2002 XW93

and 5 new Centaur/SDO discoveries:

2002 VQ94, 2002 QX47, 2002 VR130, 2002 VG131, 2002 XU93

Reclassified objects:

2002 GG32 (TNO  $\rightarrow$  SDO)  
2000 YU1 (SDO  $\rightarrow$  TNO)  
2002 VQ94 (Centaur  $\rightarrow$  SDO)

Objects recently assigned numbers:

1998 QM107 = (49036)  
1995 TL8 = (48639)  
1999 RA215 = (49673)  
2002 LM60 = (50000)

Objects recently assigned names:

2002 LM60 = Quaoar

Current number of TNOs: 651 (and Pluto & Charon, and 8 other TNO binary companions)

Current number of Centaurs/SDOs: 127

**Orbit Distribution Nature of Kuiper Belt Objects**

**The Plane of the Edgeworth-Kuiper Belt**

Simon J. Collander-Brown<sup>1</sup>, Mario D. Melita<sup>2</sup>,  
Iwan P. William<sup>2</sup>, and Alan Fitzsimmons<sup>1</sup>

<sup>1</sup> Queens University Belfast, Belfast BT7 1PX, UK

<sup>2</sup> Queen Mary, University of London, E1 4NS, UK

We examine possible locations for the primordial disk of the Edgeworth-Kuiper Belt (EKB), using several subsets of the known objects as markers of the total mass distribution. Using a secular perturbation theory, we find that the primordial plane of the EKB could have remained thin enough to escape detection only if it is clustered very closely about the invariant plane of the Solar System.

**Dynamics of the Edgeworth-Kuiper Belt beyond 50 AU:  
Spread of a Primordial Thin Disk**

Adrián Brunini<sup>1</sup>

<sup>1</sup> Observatorio Astronómico, Universidad Nacional de La Plata, and IALP-CONICET, Paseo del Bosque S/N, 1900, La Plata, Argentina

In this paper we report numerical simulations of the dynamical evolution of the region  $a > 50$  AU. We found that some dynamical effects such as high-order secular resonances with the rate of precession of Neptune's node of the form  $k\dot{\Omega} - \dot{\Omega}_{Nep}$  with  $k = 4, 5, \dots$  or combined mean motion resonances with Uranus and Neptune of the form  $kn_N + jn_U + mn \sim 0$  may spread a very thin primordial disk in this region after 4.5 Gy of evolution by a factor of up to 2.

# The Existence of a Planet Beyond 50 AU and the Orbital Distribution of the Classical Edgeworth-Kuiper-Belt Objects

A. Brunini<sup>1</sup> and M.D. Melita<sup>2</sup>

<sup>1</sup> Observatorio Astronómico, Universidad Nacional de La Plata, and IALP-CONICET, Paseo del Bosque S/N, 1900, La Plata, Argentina

<sup>2</sup> Astronomy Unit, School of Mathematical Sciences, Queen Mary, University of London, Mile End Road, London E1 4NS, United Kingdom

We study the effects of a Mars-like planetoid with semimajor axis at about  $\sim 60$  AU orbiting embedded in the primordial Edgeworth-Kuiper Belt (EKB). The origin of such an object can be explained in the framework of our current understanding of the origin of the outer Solar System, and a scenario for the orbital transport mechanism to its present location is given. The existence of such an object would produce a gap in the EKB distribution with an edge at about 50 AU, which seems to be in agreement with the most recent observations. No object has been detected so far at low eccentricities with semimajor axes beyond 50 AU, even though, the present observing capabilities would allow an eventual detection (Gladman *et al.* 1998, Jewitt *et al.* 1998, Chiang *et al.* 1999, Allen *et al.* 2000, Trujillo *et al.* 2001, Gladman *et al.* 2001a, Trujillo and Brown 2001). Finally, ranges for the magnitude and proper motion of the proposed object are given.

## The Origin of the Kuiper Belt High Inclination Population

Rodney S. Gomes<sup>1</sup>

<sup>1</sup> GEA/OV/UFRJ, Ladeira Pedro Antônio, 43, Centro, 20.080-090 Rio de Janeiro, Brazil

I simulate the orbital evolution of the four major planets and a massive primordial planetesimals disk composed of  $10^4$  objects, which perturb the planets but not themselves. As Neptune migrates by energy and angular momentum exchange with the planetesimals, a large number of primordial Neptune scattered objects are formed. These objects may experience secular, Kozai and mean motion resonances that induce temporary decrease of their eccentricities. Because planets are migrating, some planetesimals can escape those resonances while in a low eccentricity incursion thus avoiding the return path to Neptune close encounter dynamics. In the end, this mechanism produces stable orbits with high inclination and moderate eccentricities. The so formed population together with the objects coming from the classical resonance sweeping process originate a bimodal distribution for the Kuiper Belt orbits. The inclinations obtained by the simulations can attain values above  $30^\circ$  and their distribution resembles a debiased distribution for the high inclination population coming from the real classical Kuiper Belt.

# Dynamical Models of Kuiper Belt Dust in the Inner and Outer Solar System

Amaya Moro-Martín<sup>1</sup> and Renu Malhotra<sup>2</sup>

<sup>1</sup> Steward Observatory, University of Arizona, 933 N. Cherry Ave., Tucson, AZ 85721, USA

<sup>2</sup> Department of Planetary Sciences, University of Arizona, 1629 E. University Boulevard, Tucson, AZ 85721, USA

We report several results related to the dynamical evolution of dust produced in the Kuiper Belt (KB). We show that its particle size frequency distribution in space is greatly changed from its distribution at production, due to the combined effects of radiation forces and the perturbations of the planets. We estimate the contribution of KB dust to the zodiacal cloud by calculating its number density radial profile near the ecliptic. We also study the contribution of KB dust to the population of IDPs collected at Earth, by calculating geocentric encountering velocities and capture rates. Our models show, in contrast with previous studies, that KB dust grains on Earth-crossing orbits have high eccentricities and inclinations, and therefore their encountering velocities are similar to cometary grains and not to asteroidal grains. We estimate that at most 25% in number of captured IDPs have cometary *or* KB origin; the KB contribution may be as low as 1-2%. We present the velocity field of KB dust throughout the Solar System; this, together with the number density radial profile, is potentially useful for planning spacecraft missions to the outer Solar System.

## Observations of Centaur 8405 Asbolus: Searching for Water Ice

Jennifer Romon-Martin<sup>1</sup>, Maria A. Barucci<sup>2</sup>, Catherine de Bergh<sup>2</sup>,  
Alain Doressoundiram<sup>2</sup>, Nuno Peixinho<sup>3,4</sup>, and François Poulet<sup>5</sup>

<sup>1</sup> LESIA, Observatoire de Paris-Meudon, Meudon Cedex, 92195, France

<sup>3</sup> LESIA, Obs. de Paris-Meudon, Meudon Cedex, 92195, France

<sup>4</sup> CAAUL, Observatório Astronómico de Lisboa, Lisboa, Portugal

<sup>5</sup> NASA Ames Research Center, Moffett Field, California, 94035, USA

Near-infrared spectra of Centaur 8405 Asbolus have been obtained, covering the whole rotational period. Complementary photometry and visible spectroscopy have also been performed. The aim of this project was to confirm or refute the water ice detection on one side of Asbolus reported by Kern et al. (2000 *Astrophys. J.*, 542, L155–L159). We found no absorption feature at any rotational phase of Asbolus. Our study is the first in-depth investigation of a centaur over a complete rotational period. Our results seem also to indicate that a change in the slope from 0.8 to 1.0  $\mu\text{m}$  may occur in Asbolus spectrum.

# CCD Photometry of Distant Comets. III. Ensemble Properties of Jupiter-family Comets

S.C. Lowry<sup>1</sup>, A. Fitzsimmons<sup>1</sup>, and S. Collander-Brown<sup>1</sup>

<sup>1</sup> APS Division, Department of Pure and Applied Physics, Queen's University Belfast, Belfast BT7 1NN, UK

We describe the results of a ground-based observational “snapshot” study of Jupiter-family comets in the heliocentric range  $2.29 \text{ AU} \leq R_h \leq 5.72 \text{ AU}$ . Results are presented based on observations from the 1m JKT on the island of La Palma. A total of 25 comets were targeted with 15 being positively detected. Broad-band VRI photometry was performed to determine dimensions, colour indices, and dust production rates in terms of the “A $\rho$ ” formalism. The results for selected comets are compared with previous investigations. Ensemble properties of the Jupiter-family population have been investigated by combining the results presented here with those of Lowry et al. (1999), and Lowry & Fitzsimmons (2001). We find that the cumulative size distribution of the Jupiter-family comets can be described by a power law of the form  $\Sigma(> r) \sim r^{-1.6 \pm 0.1}$ . This size distribution is considerably shallower than that found for the observed Edgeworth-Kuiper belt objects, which may reflect either an intrinsic difference at small km-sizes in the belt, or the various processes affecting the nuclei of comets as their orbits evolve from the Edgeworth-Kuiper belt to the inner Solar system. Also, there would appear to be no correlation between nuclear absolute magnitude and perihelion distance. Finally, for the sample of active comets, there is a distinct correlation between absolute R band magnitude and perihelion distance, which can be explained by either a discovery bias towards brighter comets or in terms of “rubble” mantle formation.

## Regarding the Putative Eccentricity of Charon's Orbit

S. Alan Stern<sup>1</sup>, William F. Bottke<sup>1</sup>, and Harold F. Levison<sup>1</sup>

<sup>1</sup> Department of Space Studies, Southwest Research Institute, 1050 Walnut Street, Suite 400, Boulder, Colorado 80302, USA

Based on astrometry from an orbit derived by HST imagery, Charon's orbital eccentricity has been reported to be in the range of 0.003–0.008 (Tholen & Buie 1997, Icarus, 125, 245). Solar and planetary tides are orders of magnitude too small to induce the reported eccentricity (Weissman et al. 1989, GRL, 16, 1241). This non-zero value, if correct, therefore indicates some significant forcing against the two-body tidal equilibrium value, which should formally be zero. Here we follow up on a preliminary study (Levison & Stern 1995, LPSC, 26, 841) to investigate whether the reported eccentricity of Charon's orbit could be due to gravitational perturbations by KBO flybys through the Pluto-Charon system and KBO impacts directly onto Pluto and Charon. We find it is unlikely that Charon's reported eccentricity could be caused by this effect. Although we cannot rule out some additional source of eccentricity excitation (e.g., an undiscovered satellite in the system, or a Kozai resonance), our analysis indicates it is plausible that Charon's actual orbital eccentricity is substantially smaller than the 0.003 lower limit reported previously.

# On the Origin of Binary Transneptunian Objects

S.J. Weidenschilling<sup>1</sup>

<sup>1</sup> Planetary Science Institute, 620 North Sixth Avenue, Tucson, Arizona 85705-8331, USA

The observed transneptunian binaries, with components of comparable mass and large separations, cannot be the result of collisions in the present dynamical environment of the Kuiper belt. They could be produced by collision of two planetesimals within the sphere of influence of a third body during low-velocity accretion in the solar nebula. Thus, they are primordial.

The *Distant EKO*s Newsletter is dedicated to provide researchers with easy and rapid access to current work regarding the Kuiper belt (observational and theoretical studies), directly related objects (e.g., Pluto, Centaurs), and other areas of study when explicitly applied to the Kuiper belt.

We accept submissions for the following sections:

- ★ Abstracts of accepted papers
- ★ Titles of submitted (but not yet accepted) papers and conference articles
- ★ Thesis abstracts
- ★ Short articles, announcements, or editorials
- ★ Status reports of on-going programs
- ★ Requests for collaboration or observing coordination
- ★ Table of contents/outlines of books
- ★ Announcements for conferences
- ★ Job advertisements
- ★ General news items deemed of interest to the Kuiper belt community

A L<sup>A</sup>T<sub>E</sub>X template for submissions is appended to each issue of the newsletter, and is sent out regularly to the e-mail distribution list. Please use that template, and send your submission to:

`ekonews@boulder.swri.edu`

The *Distant EKO*s Newsletter is available on the World Wide Web at:

<http://www.boulder.swri.edu/ekonews>

Recent and back issues of the newsletter are archived there in various formats. The web pages also contain other related information and links.

*Distant EKO*s is not a refereed publication, but is a tool for furthering communication among people interested in Kuiper belt research. Publication or listing of an article in the newsletter or the web page does not constitute an endorsement of the article's results or imply validity of its contents. When referencing an article, please reference the original source; *Distant EKO*s is not a substitute for peer-reviewed journals.

### **Moving ... ??**

If you move or your e-mail address changes, please send the editor your new address. If the newsletter bounces back from an address for three consecutive issues, the address will be deleted from the mailing list. All address changes, submissions, and other correspondence should be sent to:

`ekonews@boulder.swri.edu`
